

Testing Replication With Open-Source Data

Bradley Allen

DATA 510 Data Science Capstone · Summer 2026

Abstract

This project leveraged open-source data and open-source-software for replication research in psychological science. Findings included:

- Confirmatory Factor Analysis of the 21-item Depression Anxiety Stress Scale (DASS-21)
- Gender differences in personality traits
- Gender differences in experiencing depression, anxiety, and stress
- Personality as a predictor of depression, anxiety, and stress for males and females

Introduction & Motivation

Problem & question: In 2011, high rates of replication failure plunged psychological research into a crisis of public trust. This project aimed to repair that trust by testing replication using open-source data and open-source software.

Impact & stakeholders: Replicating findings of gender differences in personality and depression, anxiety, and stress will improve the knowledge base of clinicians who provide mental health treatment.

Background & Related Work

- Replication research is vital for improving our understanding of human behavior (Youyou et al., 2023).
- Replication with slight methodological changes yields equally rigorous results, and advances the psychological sciences (Nosek & Errington, 2020).
- Target studies for replication found:
 - Females tend to rate lower in emotional stability and higher in agreeableness compared to males (Weisberg et al., 2011);
 - Emotional stability is the best predictor of depression, stress, and anxiety (Uliaszek et al., 2010);
 - Confirmatory Factor Analysis (CFA) suggests DASS-21 is suitable for comparison of means between males and females (Gomez et al., 2014)

Methods & Evaluation

Approach: Analyses were conducted in R using R Studio, included R's built in independent samples t-test, and packages such as lavaan, and effectsize

Validation:

- Participants who failed an attention check were removed
- Given the large sample size:
 - Independent sample t-tests were reported by effect size
 - CFA was reported in terms of Comparative Fit Index (Furr, 2018)

Reproducibility

Repository: https://github.com/ballen-git/data510-capstone/tree/main/deliverables/final_deliverable

Results & Visualizations

- Females rated higher on trait agreeableness and lower on emotional stability compares to males ($d = .19$, $d = -.35$).
- Compared to males, females reported higher levels of depression, anxiety, and stress ($d = .10$, $d = .31$, $d = .34$, respectively).
- Emotional stability was the most influential trait for negative emotions.

DASS-21 & Personality Trait Distribution Plots

Results & Visualizations

Personality Coefficient Plot for DASS-21 Indicators

Fig 3. Distribution of standardized personality coefficients. Emotional stability is the most influential trait for personality as a predictor of stress, depression, and anxiety for both males and females.

Discussion, Limitations & Conclusions

Discussion: Results supported prior findings, adding to the “credibility revolution” described by Korbmaier et al. (2023). Therefore, this study adds to the growing body of replication studies advancing the cause of repairing public trust in the psychological sciences.

Limitations & future work: This survey was conducted online and may have been completed multiple times by the same participant. Additionally, populations with limited or no access to the internet were under sampled. Results from this study will be used to isolate important features from machine models that predict depression, stress, and anxiety in males and females.

Conclusions: This study showed open-source software can be used to conduct rigorous analysis of open-source data to replicate findings from previous research, thus opening the field of psychological science to a broad swath a researchers looking to contribute to the credibility revolution.
